# Outline

- 1 ECOH
  - Background
  - Evolution
  - Implementation
  - CFV
- 2 One-Up Problem for ECDSA
- 3 Conclusion

# Elliptic Curve Only Hash

## Definition (High level)

Pad message block  $M_i$  into a point  $P_i$ .

$$T = \sum_i P_i \quad (1)$$

Do the same for  $T$ . Truncate to get hash  $H$ .

# Motivation: SHA-3

- Wang, Feng, Lai, Yu: collision FOUND in MD5.
- Wang, Yin, Yu:  $2^{69}$  collision algorithm for SHA-1
- Wang, Yao, Yao:  $2^{63}$  collision algorithm for SHA-1
- NIST: please use SHA-2
- NIST: is SHA-2 ok?
- NIST: SHA-3 competition, AES-style
- Some like to call “AHS”

# Discrete Log Hash: CHP

Definition (Chaum, van Heijst, Pfitzmann (1991))

$$H(m, n) = mP + nQ$$

Theorem

*A collision in  $H$  gives  $\log_P(Q)$ .*

Proof.

If  $H(a, b) = H(c, d)$ , then

$$aP + bQ = cP + dQ \tag{2}$$

and solving  $\log_P(Q) = \frac{a-c}{d-b} \bmod n$ . □

# Discrete Log Hash: CHP

Definition (Chaum, van Heijst, Pfitzmann (1991))

$$H(m, n) = mP + nQ$$

Theorem

A collision in  $H$  gives  $\log_P(Q)$ .

Proof.

If  $H(a, b) = H(c, d)$ , then

$$aP + bQ = cP + dQ \tag{2}$$

and solving  $\log_P(Q) = \frac{a-c}{d-b} \bmod n$ . □

# Discrete Log Hash: CHP

Definition (Chaum, van Heijst, Pfitzmann (1991))

$$H(m, n) = mP + nQ$$

Theorem

A collision in  $H$  gives  $\log_P(Q)$ .

Proof.

If  $H(a, b) = H(c, d)$ , then

$$aP + bQ = cP + dQ \quad (2)$$

and solving  $\log_P(Q) = \frac{a-c}{d-b} \bmod n$ . □

# CHP Pros and Cons

- Provably secure assuming ECDLP hard.
- $3m/2$  EC adds per  $2m$  bits.
- Compression factor 2, must be iterated.

# Discrete Log Hash 2: MuHASH

## Definition (Bellare and Micciancio (1997))

Let  $P_i = F(i \| M_i)$ , where  $F$  is a “random oracle”. Let

$$H = \sum_i P_i \quad (3)$$

# MuHASH Advantages

- One EC add per  $m$  bits.
  - ▶ E.g. 384 times faster than CHP.
- Parallelizable.
- Incremental:
  - ▶  $H' = H - P_i + P'_i$
- Provably secure, assuming ECDLP hard and  $F$  random oracle.

# MuHASH Disadvantages

- Assumes  $F$  is a random oracle.
- Insecure if  $F$  insecure.
  - ▶ Must already have a collision-resistant  $F$ .
  - ▶ SHA-1? SHA-2? SHA-3?

# ECOH's Design Rationale

- Leverage from MuHASH:
  - ▶ Speed.
  - ▶ Parallelizability.
  - ▶ Incrementality.
- Avoid reliance on pre-existing  $F$ .

# EECH

- Replace  $F$  by fixed key block cipher:

$$H = \sum_i F(i \| M_i) \quad (4)$$

- Encrypted Elliptic Curve Hash (EECH) born.
- No collisions in  $F$ , guaranteed.
- Model  $F$  by ideal cipher.
- Rehash Bellare and Micciancio's security proof.

# EECH

- Replace  $F$  by fixed key block cipher:

$$H = \sum_i F(i \| M_i) \quad (4)$$

- Encrypted Elliptic Curve Hash (EECH) born.
- No collisions in  $F$ , guaranteed.
- Model  $F$  by ideal cipher.
- Rehash Bellare and Micciancio's security proof.

# EECH

- Replace  $F$  by fixed key block cipher:

$$H = \sum_i F(i \| M_i) \quad (4)$$

- Encrypted Elliptic Curve Hash (EECH) born.
- No collisions in  $F$ , guaranteed.
- Model  $F$  by ideal cipher.
- Rehash Bellare and Micciancio's security proof.

# EECH

- Replace  $F$  by fixed key block cipher:

$$H = \sum_i F(i \| M_i) \quad (4)$$

- Encrypted Elliptic Curve Hash (EECH) born.
- No collisions in  $F$ , guaranteed.
- Model  $F$  by ideal cipher.
- Rehash Bellare and Micciancio's security proof.

# EECH

- Replace  $F$  by fixed key block cipher:

$$H = \sum_i F(i \| M_i) \quad (4)$$

- Encrypted Elliptic Curve Hash (EECH) born.
- No collisions in  $F$ , guaranteed.
- Model  $F$  by ideal cipher.
- Rehash Bellare and Micciancio's security proof.

# Oops: Not 1-way

- Unlike MuHASH,  $F$  now invertible.
- If adversary knows  $M_1$  and  $M_3$  but not  $M_2$ , then

$$2\|M_2 = F^{-1}(H(M_1, M_2, M_3) - F(1\|M_1) - F(3\|M_3)) \quad (5)$$

# Oops: Not 1-way

- Unlike MuHASH,  $F$  now invertible.
- If adversary knows  $M_1$  and  $M_3$  but not  $M_2$ , then

$$2\|M_2 = F^{-1}(H(M_1, M_2, M_3) - F(1\|M_1) - F(3\|M_3)) \quad (5)$$

# Fix it up.

- Post-process with one-way function?
  - ▶ Scalar multiply?
  - ▶ EECH again?
  - ▶ Pairing?
  - ▶ Checksum in extra block?
- Seems to thwart block inversion attack.
- Interferes with incrementality.

# Ouch: Not collision resistant!

Let

$$2\|D = F^{-1}(F(1\|A) + F(2\|B) - F(1\|C)) \quad (6)$$

Probability of index 2 appearing depends its bit length. Try that many  $C$  values, until it works.

Then

$$F(1\|A) + F(2\|B) = F(1\|C) + F(2\|D), \quad (7)$$

i.e. a collision  $H(A, B) = H(C, D)$ .

Second preimage attack!

# Fix it again.

- Pad  $M_i$ , before applying  $F$ .
- If  $F$  random enough, inverting will not give requisite padding.

# ECOH

- Now that EECH is all fixed ...
- just set  $F$  to the identity function.
- Elliptic Curve Only Hash.

# ECOH

- Now that EECH is all fixed ...
- just set  $F$  to the identity function.
- Elliptic Curve Only Hash.

# ECOH

- Now that EECH is all fixed ...
- just set  $F$  to the identity function.
- Elliptic Curve Only Hash.

# ECOH vs. EECH

- Purity of ECOH.
- No dependence on ideal cipher model.
- No performance cost of enciphering.
  - ▶ ECOH is already slow enough.
- Is it more crazy to:
  - ▶ encrypt with a fixed key,
  - ▶ do nothing?

# ECOH vs. EECH

- Purity of ECOH.
- No dependence on ideal cipher model.
- No performance cost of enciphering.
  - ▶ ECOH is already slow enough.
- Is it more crazy to:
  - ▶ encrypt with a fixed key,
  - ▶ do nothing?

# ECOH vs. EECH

# ECOH Security Proof?

- Generic group model!
  - ▶ Detailed version in progress.
- Big deal ...

# ECOH Security Attack!?!

- Semaev summation polynomial

$$f_n(X_1, \dots, X_n) = 0$$

if and only if there exist  $Y_i$  with

$$(X_1, Y_1) + \dots + (X_n, Y_n) = 0.$$

- Degree in each variable  $2^{n-2}$

# Second Preimage Attack on ECOH

- Given  $X_3$  and  $X_4$ .
- Find  $X_1$  and  $X_2$ , such that

$$(X_1, Y_1) + (X_2, Y_2) = (X_3, Y_3) + (X_4, Y_4)$$

which implies

$$f_4(X_1, X_2, X_3, X_4) = 0$$

- Total degree  $2(2^4 - 2) = 4$ .
- $X_i = c_i Z_i + d_i$ , where  $Z_i$  has low degree.

$$g(Z_1, Z_2) = 0$$

# Security Proof???????

- Semaev: low degree solutions to Summation polynomials can be used to solve ECDLP.
- Contrapositive: if ECDLP hard, then hard to find low degree solutions.
- But: ECOH degrees much higher than Semaev degrees.

# Security Proof??????

- Semaev: low degree solutions to Summation polynomials can be used to solve ECDLP.
- Contrapositive: if ECDLP hard, then hard to find low degree solutions.
- But: ECOH degrees much higher than Semaev degrees.

- Contrapositive: if ECDLP hard, then hard to find low degree solutions.
- But: ECOH degrees much higher than Semaev degrees.

# Curve Choice

- NIST recommended curves:
  - ▶ B-283,
  - ▶ B-409,
  - ▶ B-571.

# Why Binary?

- $y$  solved by quadratic equation involving  $x$  containing padded message block.
- Quadratic equations faster in binary fields than in prime fields
  - ▶ Use linear half-trace function (not square root)
  - ▶ Use look up tables.
- Bonus: Intel announced AVX will include binary polynomial multiplier.

# Why Binary?

  - ▶ Use linear half-trace function (not square root)
  - ▶ Use look up tables.
- Bonus: Intel announced AVX will include binary polynomial multiplier.

# Reference implementation

- Coded by Matt J. Campagna (who also helped with specification of ECOH details)
- Features:
  - ▶ Bit lookups for trace function
  - ▶ Table lookups for squaring and half-trace
  - ▶ Basic shift-and-xor polynomial multiply
  - ▶ Affine coordinates
- Rate on a desktop: 0.14 MB/s

# Possible optimizations

- Other coordinates?
  - ▶ Not predicted to help.
- Better multiplication:
  - ▶ Should help somewhat.
- Simultaneous inversions:
  - ▶ Each solving for  $y$  requires inversion.
  - ▶ Each addition requires inversion.
  - ▶ These can be replaced a few inversion and a corresponding number of multiplies.
  - ▶ Predicted speedup: maybe five times?
- Parallelization

# Hash with a Twist

- Bernstein:  $x$ -only DH with “invalid”  $x$  thrown to the twist.
- EECH/ECOH: every  $x$  maps to a point on curve or its twist
- Get one total and twisted total
- Sum these on curve over quadratic extension.

# Dreaming doesn't hurt

0.14 MB/s

x 5 (simultaneous inversion, etc.)

x 10 (Intel AVX)

x 10 (ten CPU multicore)

=

70 MB/s

Faster than SHA-1?

# Convertible Group

## Definition

A group  $G$  and a function  $f : G \rightarrow \mathbb{Z}$ .

- Use multiplicative notation for  $G$ .
- Call  $f$  the conversion function.

# One-Up Problem

## Definition

Given  $a, b \in G$ , find  $c$  such that

$$c = ab^{f(c)} \quad (8)$$

- One is up:  $a^1$ .
- One  $c$  is up.

# Convertible DSA

## Definition

Let  $g \in G$  have order  $n$ . Let  $h : \{0, 1\}^* \rightarrow \mathbb{Z}$  be a hash function. Then  $(r, s)$  is a valid signature on message  $m \in \{0, 1\}^*$  under public key  $y \in G$ , only if  $\gcd(s, n) = 1$  and

$$r = f \left( (g^{h(m)} y^r)^{1/s \bmod n} \right). \quad (9)$$

- Includes DSA.
- Includes ECDSA.

# So what's up with this problem?

## Theorem

*If the one-up problem for  $(G, f)$  is solvable, then Convertible DSA for  $(G, f, g, h)$  is forgeable.*

# Hard up?

## Conjecture

*For the  $(G, f)$  in ECDSA, solving the 1-up problem costs about  $n$  group operations and conversions.*

# Up's enough?

## Conjecture

*Convertible DSA resists universal forgery against key-only attacks (UF-KOA) if*

- 1 *Discrete logs hard in  $G$ .*
- 2 *One up hard in  $(G, f)$ .*
- 3 *Hash  $h \bmod n$  is rarely zero.*

*More powerful forgery attacks resisted if hash has further security properties (e.g. collision resistance).*

# Up over log?

- If discrete logs easy, ...
- Can one-up problem be hard?
- Maybe, if  $f$  ...
- is random oracle.

# Up under log?

- In generic group model,
- If adversary gets access to one-up oracle, then
- Discrete logs still hard.

# Semilog problem

## Definition (ECC 2001, Advances in ECC)

A semilog of  $y$  is a pair  $(r, s)$  which would be valid signature under public key  $y$  if the message had hash equal to one.

## Theorem (ECC 2001/Advances in ECC)

*ECDSA resists UF-KOA if and only if semilog is hard and hash is rarely zero.*

# Semilog = Fork(Log, 1up)

## Theorem

*The semilog problem, with one component is fixed, is equivalent to*

- *the discrete log problem if  $r$  is fixed.*
- *the 1-up problem if  $s$  is fixed.*

# Diffie-Hellman Disguised as One-Up

- If  $f(x) = \log_g(x)$ , then
- One-up problem equivalent to DHP
- This  $f$  is impractical, so
- result is only theoretical.

# One-Up as Obstacle

- Pointcheval and Stern couldn't prove ECDSA secure in random oracle model, assuming only hard log.
- Paillier and Vergnaud argued ECDSA couldn't be proved secure in the random oracle model, assuming hard log (unless one-more log problem was easy).
- Perhaps one-up problem was hidden obstacle.
- Not possible to prove ECDSA secure given only hard log, because one-up could be easy.
- In practice, though, one-up seems harder than log!

# One-Up as Obstacle

# ECDSA with ECOH

- No bit twiddling — pure algebra.
- Use the same curve for both.

# Conclusion

- ECC: not just for PKC and RNGs, anymore!
- ECOH: who needs need bit twiddling, now?
- ECDSA: One-up? Okay.
